In reaction mechanism: Kinetic isotope effects. Isotopes are atoms that have the same atomic number (and, hence, generally the same chemistry) but different mass. The difference in mass becomes chemically important in certain instances. For example, when a carbon-hydrogen bond is replaced by a carbon-deuterium bond (deuterium being... [Read More](#)

As the title suggests, Isotope Effects in the Chemical, Geological and Bio Sciences deals with differences in the properties of isotopically substituted molecules, such as differences in the chemical and physical properties of water and the heavy waters.

Isotope effects, mostly involving hydrogen-deuterium, are one of the most powerful tools for chemical kinetics investigations. The kinetic isotope effect is defined as the ratio of the rate constants corresponding, respectively, to the unlabeled and to the labeled species at a given internal energy, that is,  $k_H(E)/k_D(E)$ .

As the title suggests, Isotope Effects in the Chemical, Geological and Bio Sciences deals with differences in the properties of isotopically substituted molecules, such as differences in the chemical and physical properties of water and the heavy waters. Isotope effects on the rates of chemical reactions, including enzyme catalyzed reactions, are treated in some detail.

Isotope effects are particularly useful in the study of DNA and RNA, as ring current effects, which would dominate structural interpretations of chemical shifts, play no role. LiWang et al. [19] have measured isotope effects across hydrogen bonds,  $^2\text{C}2(\text{ND})$ , in A-U and A-T base pairs (See Fig. 2 ).

In physical organic chemistry, a kinetic isotope effect (KIE) is the change in the reaction rate of a chemical reaction when one of the atoms in the reactants is replaced by one of its isotopes. Formally, it is the ratio of rate constants for the reactions involving the light ( $k_L$ ) and the heavy ( $k_H$ ) isotopically substituted reactants (isotopologues):

Primary effects are invariably normal, that is, the light isotope reacts faster than the heavy one. Secondary effects may show inverse behavior when the reaction is characterized by an increase in bonding and the difference in zero-point energies in the transition state is greater than in the reactant state.

The nuclide concept (referring to individual nuclear species) emphasizes nuclear properties over chemical properties, whereas the isotope concept (grouping all atoms of each element) emphasizes chemical over nuclear. The neutron number has large effects on nuclear properties, but its effect on chemical properties is negligible for most elements.

It allows isotope effects to be measured for all the positions in one of the reactant molecules by running the reaction close to completion and then recovering unreacted reactant and measuring the changes in its isotope abundances using NMR. The method has since been widely applied, and improved. H
