Fluids affect the movement of chemicals and heat in the crust, and they are the major factor in the formation of hydrothermal ore deposits. Yet, fluids have been overlooked in many geologic investigations.

The extracellular fluid can be further divided into interstitial fluid, plasma, lymph, cerebrospinal fluid, and milk (in mammals). Extracellular fluids bathe the cells and conduct nutrients, cells, and waste products throughout the tissues of the body. Mature red blood cells, white blood cells, and platelets lie in a nearly colourless, protein-rich liquid called plasma.

In a solid, shear stress is a function of strain, but in a fluid, shear stress is a function of strain rate.A consequence of this behavior is Pascal's law which describes the role of pressure in characterizing a fluid's state.. Depending on the relationship between shear stress, and the rate of strain and its derivatives, fluids can be characterized as one of the following:

The Three Major Roles of Electrolytes in the Human Body 1. Fluid Balance for the Maintenance of Homeostasis. Fluid balance is important in the maintenance of homeostasis in the human body. Note that homeostasis is the state of steady internal conditions needed to maintain proper body functioning.

Fluid and Electrolyte Balance. The kidneys are essential for regulating the volume and composition of bodily fluids. This page outlines key regulatory systems involving the kidneys for controlling volume, sodium and potassium concentrations, and the pH of bodily fluids. A most critical concept for you to understand is how water and sodium regulation are integrated to defend the body against all possible disturbances in the volume and osmolarity of bodily fluids.

Normal cellular function requires that the intracellular composition of ions, small molecules, water, pH, and a host of other substances be maintained within a narrow range. This is accomplished by the transport of many substances and water into and out of the cell with the use of membrane transport proteins as described in Chapter 1.

Since atherosclerotic plaques tend to be localized at sites of branching and artery curvature and since these locations would be expected to harbor complex flow patterns, investigators postulated that fluid dynamics might play an initiating role in atherogenesis. Several fluid dynamic variables were proposed as initiating factors.

If the idea of having to drink lots of cups of water a day doesn't appeal, don't worry fluids include fresh water and all other liquids, such as milk, coffee, tea, soup, juice and even soft drinks. Fresh water is the best drink because it does not contain energy (kilojoules) and is best for hydrating the body.

The fluid responsible for hydrothermal REE redistribution is preserved in fluid inclusions in the quartz lenses. The bulk of the quartz lacks fluid inclusions but is cut by two later hydrothermal quartz generations, both containing sulfate-rich fluid inclusions with sulfate often present as multiple trapped solids, as well as in solution.
